

Task search filter bug

Issue - Search with status filter was not working properly.
Sometimes archived tasks were also coming or the status filter was getting ignored.

How I found it -

- tested search with different combinations of filters.
- noticed results didn't match what was ~~being~~ expected.
- checked the query in repository and saw the AND/OR conditions were not grouped properly.

Fix -

- grouped the title and description search conditions together (title like ... OR description like ...).
- then applied archived = false and status filter to the whole condition.

Why -

- So that every search result is unarchived ~~and~~ and also matches the selected status when a filter is applied.

Result -

- Search and status filtering now work together properly. No unwanted tasks show up.

②

Note 2

Issue : Search was slow ~~clear~~ because there was an artificial delay added in the code based on the query length / complexity.

How I found :

- noticed that search requests were always taking extra time.
- checked the code and found a sleep / delay which was increasing with query length.

Fix :

- removed the artificial delay.
- also removed the unnecessary calculation related to query complexity.

Result :

- Search now works normally without any extra waiting time.

Pagination validation

Issue : Pagination parameters were not properly validated. If invalid values were passed it could lead to incorrect behaviour or unexpected results.

How I found :

- tested the API with different values for page and page size.
- tried giving page = 0 and very large page size and noticed it was still being processed.

Fix :

- added validation for page and pageSize
- page should be ≥ 1
- pageSize should be within a reasonable range (1 to 100) ~~✗~~

Why : To prevent invalid input from reaching the pagination logic ~~and~~ to ensure stable and predictable ~~and~~ behaviour.

Result : Invalid pagination requests now return 400 Bad Request.

Invalid status handling

Issue : When an invalid status value was passed, it ~~likes~~ causing an exception and returning a server error instead of a proper client response.

How I found :

- tested the API with a random / invalid status value.
- saw it was throwing an exception ~~and~~ and returning a 500 error.

Fix :

- added validation for the status parameter.
- if the value is not one of the allowed statuses, return 400 Bad Request.
- handled the invalid value before calling the enum conversion.

Why : ~~that~~ invalid input from client should not cause a server error. It should be handled properly with a clear message.

Result : - Invalid status requests now return

Pagination reset on filter change

Issue : When changing search or status filter while being on a later page, it was sometimes showing no results even though ~~there~~ there were matching tasks.

How I found :

- tested search with some keyword while on page 2 (or higher).
- saw that the results list was empty even though matching tasks existed ~~on~~ on page 1.

Fix :

- reset the page number to 1 whenever the search query or status filter changes.
- so that we always start ~~at~~ from the first page with new filters.

Why :

~~then~~ A new filter can have fewer results, so staying on a later page might not show anything. It should always start from the first page.

Result :

Search and status changes now show the correct results immediately.
